Where Do Random Numbers Come From?

Assignment Project Exam Help

- Generated from physical processes (background radiation, radio-active decay etc)

- <https://eduassistpro.github.io>

- Hard to model.

- Computer generated *pseudo-random*

- Deterministic (you'll get the same answer starting point), but looks close to random.

Congruential Generators

Simplest effective pseudo-random number generator

$$X_{n+1} = (AX_n + B) \pmod{m}$$

- <https://eduassistpro.github.io>
- Will only repeat after m steps if
and $A - 1$ is divisible by prime factors of
- To obtain uniform pseudo-random num
- Need to be cautious; can detect a deterministic relationship.
- **But** determinism can also be helpful (see later).

Example

JMR recommends

```
X[1] = 3
```

```
A = 1664525
```

```
B = 1013
```

```
m = 23
```

```
for(
```

But Take Care

The RANDU generator was shipped with Unix systems in the 1970s, using

$A = 65539$

$B = 0$

$m = 2^{31}$

Plott
evid

- Power of 2 used for m because con arithmetic (very low-level computing)
- RANDU chosen also for convenience – prob because simulation results did not match theory.
- Period is $2^{32} = 4,294,967,296$ before repeating numbers; usually enough.

In R

Assignment Project Exam Help

- Congruential generators a good first start, now somewhat absolute.

- Observable correlation between X and X (eg as in

- <https://eduassistpro.github.io>

-

representation for X_k .

- R uses the *Mersenne-Twister* (dev along these lines

- Period is $2^{19937} - 1$ (not storable in R).
- Plots of 623-dimensional runs (if you can think of this) still look uniform.

Seeds and Repeatability

- Pseudo-random number generators are *deterministic*: if you start them in the same place, you get the same answer.
- Typically, R chooses a 'seed' as a starting point; often from system clock.

<https://eduassistpro.github.io>

```
> set.seed(36)
```

```
> runif(5)
```

```
[1] 0.6223777 0.6754986 0.8022900 0
```

```
> runif(5)
```

```
[1] 0.01990291 0.95542781 0.43666244 0.08922046 0.360519
```

- Instead of storing everything in a simulation, this lets you re-run it *exactly*.
- Often simulation time mitigates against this, but it can be convenient.

R and Seeds

- Besides `set.seed`, R also stores `.Random.seed`.

- This is a vector of 626 integers that also specify parts of the random number generator.

- `set.seed(123456789)` is equivalent to `set.seed(.Random.seed)`.

```
> RNG.seed
> runif(5)
[1] 0.80228995 0.26030829 0.75976074 0.01990291 0.95542781
> .Random.seed = RNG.seed
> runif(5)
[1] 0.80228995 0.26030829 0.75976074 0.01990291 0.95542781
```

Also doesn't require you to make up an integer. Works for any simulation (as long as you do exactly the same commands).

From Uniform to Discrete Random Variables

From here on assume we can generate $U(0, 1)$ random variables – how do we get to others?

■ For Bernoulli random variables with $B(p)$, then if $U \sim U(0, 1)$,

$$P(U < p) = p$$

■ <https://eduassistpro.github.io>

Add WeChat $\sum_{i=1}^n P$ edu_assist_pro

We can generate X by taking U

$$X : F(X - 1) < U \leq F(X)$$

Then

$$P(F(X - 1) < U \leq F(X)) = F(X) - F(X - 1) = P(X)$$

Example

Simulating from a Poisson:

```
U = runif(1)
X = 0
while( ppois(X,3) < U){ X = X+1 }
```

See code
distribution

Often $F(X)$ is not easy to calculate, but
update $F(X)$ within the while loop:

```
U = runif(1)
X = 0
FX = dpois(0,3)
while( FX < U){ X = X+1; FX = FX + dpois(X,3) }
```

`dpois` much cheaper than `ppois` to calculate.

Some Special Cases

There are often constructive definitions of r.v.'s that can be employed.

- Binomial random variables are a sum of independent Bernoulli's: $X \sim \text{Bin}(n, p) \Rightarrow X = \sum_{i=1}^n Z_i$ where

<https://eduassistpro.github.io>

- Geometric or negative binomials – see exer
- Uniform on the integers $1, \dots, M$; u

```
> N = 100; n = 10;  
> ceil( N*runif(n) )  
[1] 75 51 13 27 92 20 45 20 8 61
```

- We can now generate bootstrap samples:

```
I = ceil( nrow(faithful)*runif(nrow(faithful)) )  
faithboot = faithful[I,]
```

Generating Permutations

Not so simple, because we only want each element once

- 1 Select one item in turn and add it to the new set.

- 2

```
N = 10; E = 1;
for(
  k = ceil( length(I)*runif(1) )
  Iperm[i] = I[k]
  I = I[-i]
}
```

You could also do this by swapping elements.

Continuous Random Variables

Assignment Project Exam Help

The *inversion* method is the simplest way to generate continuous random variables

We know

$F(X)$

as F

then

it can

<https://eduassistpro.github.io>

Add WeChat edu_assist_pro

Only problem is that $F^{-1}(x)$ easy to obtain

Important Special Cases

Uniform $U(a, b)$ Density: $I(x \in [a, b]) / (b - a)$

cdf $F(x) = (x - a) / (b - a)$ if $a \leq x \leq b$

inverse cdf $F^{-1}(U) = (b - a)U + a$

Exponential $\exp(\lambda)$ Density $\lambda e^{-\lambda x}$

Assignment Project Exam Help

<https://eduassistpro.github.io>

Uniform

Inverse CDF

Exponential(1)

Add WeChat edu_assist_pr

Rejection Method

When F^{-1} is not easy to calculate explicitly – could try numerically.

Alternatively, rejection method is sometimes faster. Simplest case:

- $X \sim f(\cdot)$ with support on $[a, b]$ and $f(x) \leq k$.
- Generate $Y \sim U(a, b)$ and $Z \sim U(0, k)$.
-

<https://eduassistpro.github.io>

Add WeChat $\frac{P(y)}{y} = \frac{\int_y^{y+\delta} f(x) dx}{\int_a^b f(x) dx}$

Because Y, Z uniform on the square.

In Code

We'll use a $Beta(1, 1.3)$ distribution. This has maximum value 1.3.

```
X = rep(0, 1000)
for(i in 1:1000){
  Accept = FALSE
  wh
  if( Z < dbeta(Y,1,1.3) ){
    Accept = TRUE
  }
  X[i] = Y
}
```

Che

```
Y = runif(1000)
Z = runif(1000,0,1.3)
Accept = Z < dbeta(Y,1,1.3)
X = Y[Accept]
```

Generalized Rejection Method

- For densities on the whole real line, we can't use a uniform distribution.

Assignment Project Exam Help

- But if we can simulate from $h(x)$ where $kh(x) > f(x)$ we can use the same ideas.

<https://eduassistpro.github.io>

Add WeChat edu_assist_pro

Call $kh(x)$ the *envelope* for $f(x)$.

- 1 Generate $Y \sim h(\cdot)$
- 2 Generate $Z \sim U(0, kh(Y))$
- 3 Accept Y if $Z < f(Y)$

Justification

General rejection method is justified because the (Y, Z) pairs are uniformly distributed over the region below $kh(x)$.

Assignment Project Exam Help

$P(($

$https://eduassistpro.github.io$

$= dzdy/k$

because $P(Z \in (z, z + dz) | Y \in (y, y + dy)) = dzdy/k$
[0 $kh(y)$].

Add WeChat edu_assist_pro

This means the points we accept are uniformly distributed on the region under $f(x)$ and therefore the x -coordinates have density $f(x)$.

Example

- In picture above, we used a Laplace distribution $h(x) = \frac{1}{2}e^{-|x|}$ as an envelope for standard normal.
- To generate from Laplace, use $V \sim B(0.5)$ and $U \sim U(0, 1)$,

<https://eduassistpro.github.io>

- To find k , ratio of densities is

$$\frac{\frac{1}{\sqrt{2\pi}}e^{-x^2/2}}{\frac{1}{2}e^{-|x|}} = \frac{\sqrt{2}}{\sqrt{\pi}}e^{-\frac{|x|}{\sqrt{2}}}$$

Note: JMR does 1/2 normal, and then uses $2(V - 0.5)$ to symmetrize.

Example Continued

We'll fix the size of Y and Z and just see how many X we get after rejection:

```
V = 2*((runif(1000)>0.5)-0.5) # Generate Laplace r.v.'s
U = runif(1000)
Y = V*10

# Unif
Z = runif(100)*exp(-abs(Y))*sqrt(2*

# Which are accepted?
Accept = Z < dnorm(Y)

# Now we get our sample
X = Y[Accept]
```

Efficiency

- In last example above, we accept about 75% of tries.
- Higher acceptance probability = less computational work.

- Over-all acceptance rate = $\int_0^1 f(x) dx / k$ (area under $kh(x) = k$, area under $f(x) = 1$).

- $\int_0^1 f(x) dx / k$

- <https://eduassistpro.github.io>

Add WeChat edu_assist_pro

- Choice of $h(x)$ (harder)

- Choice of k .

- See optimizing Gamma in book (and on the board).

Normal Random Variable Methods

Note if $X \sim N(0, 1)$, then $\sigma X + \mu \sim N(\mu, \sigma^2)$, easy once we can generate $N(0, 1)$.

1 Improved rejection methods from above

■ In fact, $Z \sim U(0, \frac{2e/\pi e^{p^2/2}}{e^{p^2/2}}) = U(0, \frac{2e/\pi}{e^{p^2/2}})$

■ We can also throw away V and just decide to make Y

■ <https://eduassistpro.github.io>

otherwise repeat.

2 Central limit theorem $\text{Var}(U) =$

$$\left(\sum_{i=1}^{12} U_i \right) - 6 \approx N(0, 1).$$

12 is a bit small; could add more terms + rescale, but this is computationally expensive.

Assignment Project Exam Help

Remember, direct transforms are generally fastest.

Exponential $(\log U)/\lambda$ if $U \sim U(0, 1)$.

<https://eduassistpro.github.io>

$B(n, p) \prod_{i=1}^n Z_i$ if $Z_1, \dots, Z_n \sim B(p)$.

$\chi^2_d \sim \sum_{i=1}^d X_i^2$ if $X_1, \dots, X_d \sim N(0, 1)$
 $F_{d_1, d_2} \sim (Z_{d_1}/d_1)/(Z_{d_2}/d_2)$ if $Z_{d_1} \sim \chi^2_{d_1}$ and $Z_{d_2} \sim \chi^2_{d_2}$

Many many other relationships; some derived, some constructed.

Box-Muller for Gaussians

Assignment Project Exam Help

- Clever construction method. Look at pairs of Gaussians (X, Y) .

- $$X = \sqrt{-2 \log U_1} \cos(2\pi U_2), \quad Y = \sqrt{-2 \log U_1} \sin(2\pi U_2)$$

- <https://eduassistpro.github.io> and $\sqrt{-2 \log U_1}$ are Gaussian!

This yields the following

- 1 $U_1, U_2 \sim U(0, 1)$
- 2 $X = \sqrt{-2 \log U_1} \cos(2\pi U_2), \quad Y = \sqrt{-2 \log U_1} \sin(2\pi U_2)$

To obtain independent normal $X, Y \sim N(0, 1)$.

More Efficient Box-Muller

Trigonometric functions are expensive.

- Instead, if (A, B) uniform on the circle with polar coordinates (S, Ψ) , $S^2 = A^2 + B^2 \sim U(0, 1)$ (again not obvious).

- (R, Θ) .

- <https://eduassistpro.github.io>

Improved algorithm is

- 1 $U, V \sim U(-1, 1)$ (uniform on box)

- 2 If $S^2 = U^2 + V^2 > 1$ retry (rejection)

- 3 Set $W = \sqrt{(-2 \log S^2)/S^2}$

- 4 $X = UW, Y = VW$.

Summary

Assignment Project Exam Help

- Random number generation actually *pseudo*-random.

■

- <https://eduassistpro.github.io>

- 1 transforms

- 2 rejection methods

- 3 being very clever

- Next: Monte Carlo integration.
